

Resilience Assessment of Ukraine's Banks

2025

In 2025, the NBU once again assessed the resilience of Ukraine's banks and banking system. For the first time since the full-scale invasion, the resilience assessment included stress-testing under an adverse scenario. The December [Financial Stability Report](#) outlines the overall results of the resilience assessment. Below are the results of the resilience assessment of individual banks, specifically the higher required capital adequacy ratios set for them. The banks that had higher requirements set for them under the baseline scenario must achieve them by the end of 2025, and under the adverse scenario, by October 2026, by implementing respective restructuring programs.

Figure 1. Weighted average estimates of the regulatory capital adequacy ratio based on stress test results

Weighted by the volume of risk-weighted assets in each year.

The 2025 resilience assessment of the banks and the banking system conventionally came in three stages. Stage one – asset quality review (AQR) – was conducted by external auditors for all banks. Stage two – extrapolation of AQR results – is carried out only if the AQR exposes a significant number of errors in the assessment of prudential loan loss provisions. In 2025, there was no reason to extrapolate AQR results for any of the banks. Stage three – stress-testing – was conducted by the NBU only for the largest banks. These were selected based on three criteria: the volumes of risk-weighted assets, household loans, and household deposits. Stress-testing was also mandatory for the financial institutions that had higher required capital adequacy ratios set for them as a result of the 2023 resilience assessment. So, 21 banks were stress-tested.

According to AQR results, adjustments to the banks' estimated prudential provisions were either insignificant or unnecessary. Significant flaws in the assessment that led to higher required capital adequacy ratios were found in just one small bank. It was later designated insolvent. Based on stress test outcomes, nine banks with 18% of the system's assets were expected to meet higher capital adequacy ratio targets. All of these financial institutions are implementing restructuring programs to achieve and maintain higher required capital adequacy ratios.

Stress test findings should be interpreted solely in the context of their underlying assumptions. Specifically:

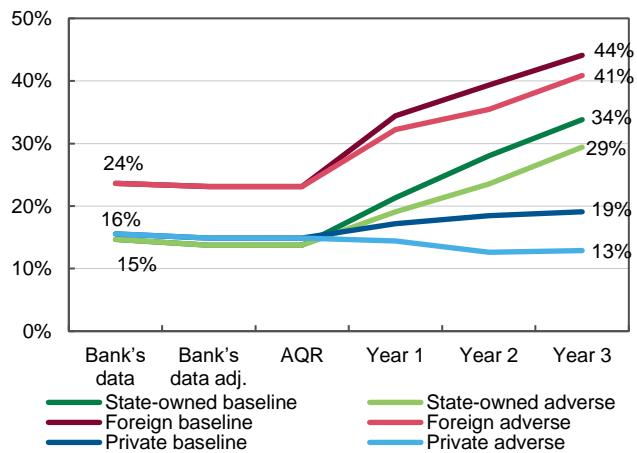

- The materialization of credit, interest-rate, FX, and operational risks was comparable in size to the consequences of the 2022 crisis.
- The banks' balance sheets were static, i.e. affected only by changes in asset quality and exchange rates. This approach is conservative, as it suggests that banks will not cut back on loans even in a crisis, although this requires holding more capital.
- The banks retained current profits throughout the forecast period. This assumption is particularly relevant for Ukraine

given the current ban on dividend distribution for all banks except state-owned ones.

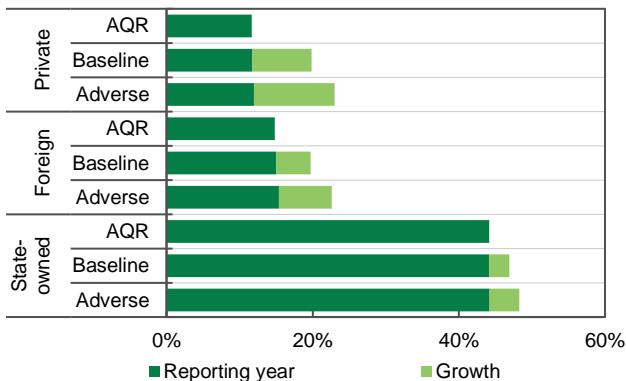

- The income tax rate was 25%, as there were no plans to change the taxation approach at the time of the resilience assessment.
- Higher required capital adequacy ratios were set for the banks due to their losses in the forecast period that led to a decrease in capital. Higher ratios were set even if the loss-making banks did not violate minimum required capital adequacy ratios.
- In 2025, higher capital adequacy ratios were for the first time defined in such a way that the banks' losses would not lead to violations of minimum required capital adequacy ratios in either scenario. Previously, higher ratios had been calculated by halving the minimum required ratios under the adverse scenario.

In the baseline scenario, the banks' regulatory capital adequacy more than doubled on average over three years, by 16.7 pp, to 32.6%. Most banks maintained profitability and were building up capital. However, for six financial institutions with 5% of sector assets, higher required capital adequacy ratios were set under the baseline scenario. As a result of stress-testing, their average regulatory capital adequacy ratio fell by 4.3 pp, to 9.1%. Five of the six banks are private Ukrainian banks, including two small systemically important ones, and one owned by a foreign banking group.

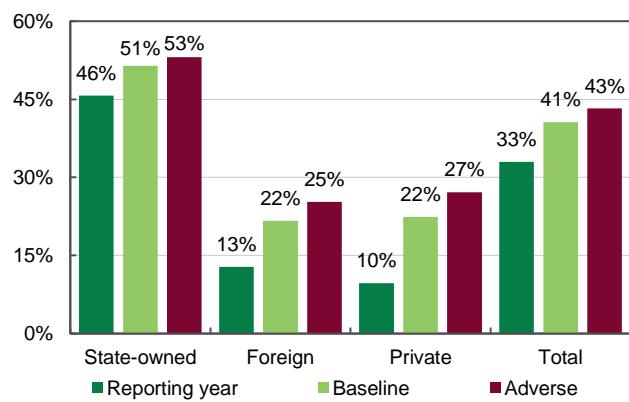

In the adverse scenario, bank capitalization as a whole grew as well, driven primarily by the profitability of the largest financial institutions. The average regulatory capital adequacy rose 12.2 pp, to 28.2%. This is a key feature that distinguishes the 2025 resilience assessment results from those of previous years, when the system's capital adequacy was declining markedly in the adverse scenario. However, nine banks had higher required ratios set for them under the adverse scenario. Six of these are the same financial institutions that needed capital under the baseline scenario. The other three are state-owned Ukreximbank and Sense Bank and private MTB Bank.

The main reason the banks made losses and needed capital was the materialization of interest rate risk. The adverse stress test scenario assumed a rise in the cost of bank funding while the yields of assets remained almost unchanged, narrowing the spread between the yield on assets and the cost of liabilities. This assumption reduced the banks' average interest margin by 2.2 pp, to 5.3%. The operational efficiency and interest margin of the banks with higher required capital adequacy ratios were worse than the system average. So, for these banks, the impact of interest rate risk was even more significant. Stress tests exposed flaws in their business models, including an overreliance on expensive concentrated short-term funding from businesses.

Credit risk had less of an impact on the results of bank stress test this year, despite the conservative assumptions. The share of defaulted loans in the adverse stress test scenario rose 10 pp, to 43%. The largest increase – 17 pp – was at private banks. For foreign and state-owned banks, the gains

Table 1. Adverse scenario for resilience assessment in 2025 and actual changes in the crisis year of 2022

Indicator	2022	Adverse scenario		
		Year 1	Year 2	In 2 years
Rate of business default	12.5%	6.6%	8.4%	14.4%
Change in net interest margin*	+1.1 pp	-1.7 pp	-0.9 pp	-2.6 pp
Losses from operational risk**	3.0%	4.0%	0.0%	4.0%

* Year-on-year. ** As a percentage of regulatory capital.

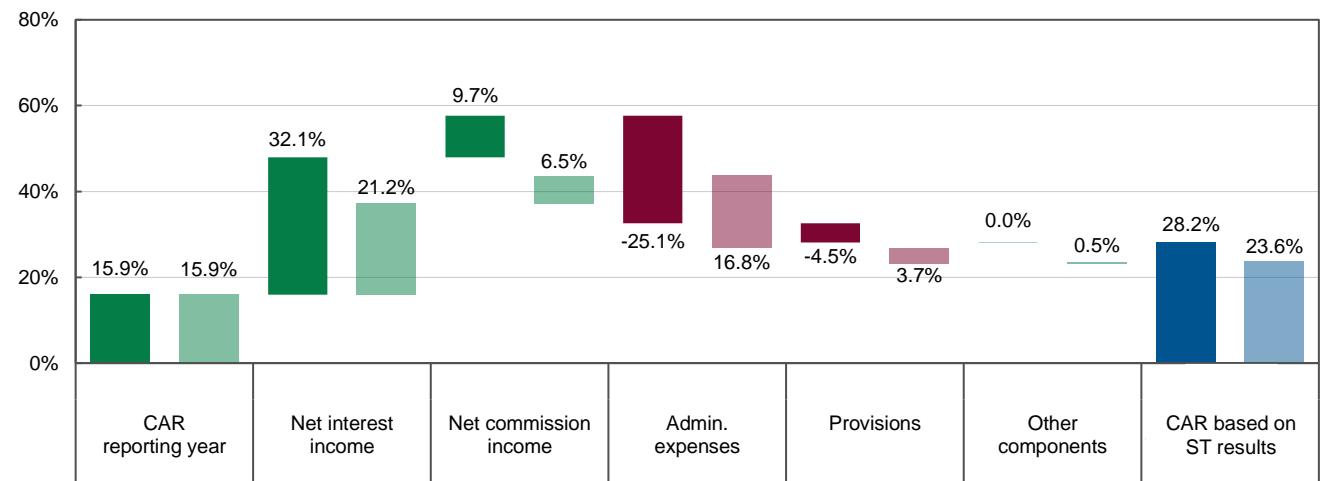

Source: NBU.

were 12 pp and 7 pp, respectively. This effect was driven by two factors: (i) the same assumption for all banks about the defaulting part of the loan portfolio, and (ii) the results of the individual stress-testing of each bank's largest borrowers. According to large borrowers' stress test results, about 10% of companies defaulted. Over the three years under the adverse scenario, the estimated size of the banks' prudential loan loss provisions (credit risk according to [Regulation No. 351](#)) rose by UAH 74 billion, or by 20% of their volume as of the reporting date (excluding FX revaluation effect). According to the stress-testing methodology, it was the size of estimated prudential provisions (not of IFRS 9 provisions) that was affecting the banks' profits. However, many banks maintained sufficient operating profitability to offset these significant credit losses.

In the first year of the adverse scenario, it was also assumed that the banks would bear the additional cost of materialized operational risk. Although losses were substantial by historical standards, they were not critically important for the profitability of any of the banks.

The banks that had higher required capital adequacy ratios set for them based on stress test results are already implementing their NBU-validated restructuring programs. The programs are being implemented in two steps. By the end of the year, the financial institutions must achieve the required capital adequacy ratios set for them under the baseline scenario, and by October 2026, under the adverse scenario. All of the programs mainly contain measures that reduce the banks' vulnerability to risks and therefore make it possible to lower required capital adequacy ratios for them. In their programs, the banks did not provide for additional capitalization by owners, but planned to build up capital through profits. The measures planned by the banks lead to a decrease in their average required regulatory capital adequacy ratios to 14.5% from 19.5% under the adverse scenario, and to 10.3% from 11.5% under the baseline scenario. The actual average regulatory capital adequacy of these banks in December 2025 is 12.5%.
